walert

Team 4 · European AI Challenge 2026 · 1st speaker: computer side

Every flood decision starts with two questions: where is the risk, and who lives there? On the computer, walert answers both, for mayors and crisis teams.

THE FULL PICTURE

One map brings together where it flooded in July 2021, the official flood zones for 1-in-100 and 1-in-500-year floods, and the gap between them: places that flooded outside the official zone.

Click a municipality and you see what a decision needs: how many buildings and residents are in the flood zone, how many of them are older, and where the shelters are, roughly how many people they hold, and, where it's known, whether a wheelchair can get in.

River gauges show how rare July 2021 was: on the Hoegne at Theux, the peak was far outside anything on record.

And walert is honest about its limits: where the models don't cover a river, the map turns grey. Not "no risk", but "not known".

BUILT ON EUROPEAN DATA

All of this comes from the challenge data, European flood maps from Copernicus and the JRC, for 66 municipalities in Wallonia, plus open sources we mark as external.

FROM THE DESK TO THE STREET

But a map on a desk doesn't reach a family on the street. That's where computer and phone connect: what the crisis team decides here goes out as a verified message to residents' phones. My teammate will show you that side.
